Field of the Invention The invention relates to a method of generating electrical power by reacting a liquid electrolyte and a reactant with a strong oxidizing agent at an anode and cathode, respectively, to generate a high temperature, high pressure combustion reaction which is used to heat a high pressure steam generator, whereby electrical power is generated as a by-product. 2. The Prior Art Several methods are known in the art for generating electrical power by the combustion of combustible materials such as coal. One of the most developed methods is that disclosed in U.S. Pat. No. 3,743,449 of G. S. Barden. The Barden process uses a geothermal heat source in a boiler as the heat source for generating steam, and in the reaction zone, the air needed for combustion is taken from the boiler. The prior art teaches that high pressure, high temperature combustion of the coal is necessary for an efficient and complete combustion of the coal to form a clean by-product gas. In an initial embodiment of the Barden process, coal is compressed and introduced into a combustion zone, wherein it reacts with air and a combustion catalyst to generate a hot carbonaceous gas. The hot gas is then delivered to a boiler in a superheated state, where it is converted to high pressure steam. The superheated steam is condensed in the boiler, producing a low pressure steam containing free entrained gas and the combustion gas. In the Barden process, the combustion gas is mixed with steam in the boiler and in a second stage combustion zone. The combined gas/steam mixture is then reheated, condensed, and delivered to a turbine/generator. A problem with the Barden process is that in order to obtain a high degree of complete combustion of the coal, the coal must be exposed to high temperature and high pressure combustion conditions. This results in high capital cost, high operating cost and a relatively large amount of undesirable pollutant emissions. Another problem with the Barden process is that the heat transfer fluid or by-product gas produced in 82157476af
